Volume 53, Issue 4

On the cover: A composite image of hyperinsulinemia fueling the fire of tumors. Pre-malignant cells in the epithelial tissue are normally eliminated via cell competition when surrounded by wild-type cells. However, upon increased secretion of insulin from the brain's insulin-producing cells (green) in *Drosophila*, cell competition is abrogated, resulting in tumorigenesis of pre-malignant cells. To find out more on how hyperinsulinemia leads to pre-malignant cells evading cell competition to drive tumorigenesis, see Sanaki et al. on pp. 379–389.
